1. INTRODUCTION

This volume contains a database of the results of the computational fluid dynamics (CFD) simulations for the research done on the National Institutes of Health *Ventilation Design Handbook on Animal Research Facilities using Static Microisolators*.

Section 1 contains an overview of the basic room configuration studied and the variations considered. It is impossible to present all the data generated by the CFD simulations. The analysis of all the results produces an enormous quantity of data that would be difficult to present and interpret in its entirety. This volume contains summaries of the data in several forms.

Section 2 contains histograms of mean values for each room considered, as they apply to both the scientists' breathing zone and the cages, for temperature, relative humidity, and CO₂ and NH₃ concentrations.

Section 3 contains rankings of the rooms based on different variables, for example, the selection of the room configuration with the lowest NH₃ concentrations in the cages.

Section 4 contains a two page summary of each room simulation, including a description of the room, mean values and standard deviations for all parameters, and histograms showing the distribution of values in the cages.

1.1 Outline of CFD Baseline Model

A typical animal research facility of average size, air change rate, rack layout, mouse population, pressurization, and so on, was modeled as the baseline model for the CFD simulations. The general features of the room are shown in figure 1.01 and are listed below.

Figure 1.01 Overall Layout of Animal Room Basecase

Description in brief

The general features of the basecase room model were:

Room: 6.10m x 3.60m x 4.22m (20' 0" x 12' 0" x 9' 0")

Door in short wall

Sink in corner

Laminar flow change station

5 racks

Cages: Microisolator (with filter top) mouse cage

5 mice per cage

Rack: Static system

6 shelves per rack

7 cages per shelf (42 cages per rack)

Supply: 2 radial supplies each providing 270cfm ($0.13\text{m}^3/\text{s}$) for a total of 15 ACH
Supply discharge temperature of $18.8\text{ }^\circ\text{C}$ ($66\text{ }^\circ\text{F}$), set such that the exhaust air temperature was $22.2\text{ }^\circ\text{C}$ ($72.0\text{ }^\circ\text{F}$)
61 percent relative humidity (to provide 50 percent RH at $22.2\text{ }^\circ\text{C}$ ($72.0\text{ }^\circ\text{F}$))

Exhausts: 2 ceiling level exhausts removing 220cfm ($0.1\text{m}^3/\text{s}$) each

Makeup Air: 100cfm ($0.047\text{m}^3/\text{s}$) coming from around the door

Overall Geometry

In the majority of the cases considered, the animal room occupied a floor area of 6.10m ($20'\text{ }0''$) x 3.66m ($12'\text{ }0''$). In some cases that were considered, the width of the room was increased from 3.66m to 4.22m ($14'\text{ }0''$). The ceiling height in all cases was 2.74m ($9'\text{ }0''$). There was only one door in the room, mounted centrally on one of the short walls.

In all the displacement ventilation systems considered in this project, air was introduced through ceiling mounted diffusers. All devices were mounted flush with the ceiling surface; there was no ductwork present within the upper room volume. The various diffuser types considered in this project were all modeled using a combination of several boundary conditions that were validated previously (see volume I, section 4.2.2). All the air exited through general exhausts. The number and locations of the exhausts were varied. In line with common practice, there was an imbalance between the amount of air supplied to the room and exhausted from the room. This leads to an overall pressurization of the room relative to the rooms or corridors surrounding the room. The relative level of pressurization was a parameter considered in this study. The makeup air to compensate for the supply/exhaust imbalance was allowed to enter or leave the room through $6.35\text{e-}3\text{m}$ ($0.25''$) gaps on three sides of the door.

The rooms considered in this project all contained five animal cage racks. The rooms also contained one of two alternative design change stations. A fuller description of these items is given below. The only other item within the room was a sink of 0.61m ($24''$) x 0.61m ($24''$) x 0.81m ($32''$) that was situated in one of the corners to the room.

In all cases, the room was considered under dark period conditions, i.e., the lights were off and produced no additional heat load to the room. Dark period conditions were chosen because early experimental work had indicated that heat, CO_2 , and NH_3 generation were higher in the dark period compared with periods in which the lights were on.

Rack Model

The overall dimensions of the rack were 1.52m ($60''$) x 0.61m ($24''$) x 1.83m ($72''$) high, as shown in figure 1.02. There were six shelves in the rack. The spacing of the shelves was 0.32m ($12.75''$) from top surface to top surface, with the lowest shelf at a height of 0.21m ($8.25''$) above the floor. The shelves were modeled as thin rectangular blocks. Details, such as the connecting ties between the shelves and the rollers on which the racks move, were not modeled because their effect on the overall flow field and gas concentration distributions was considered insignificant.

Figure 1.02 *CFD Model of Cage Rack*

Located on the shelves of the racks were representations of the animal cages, shown in figure 1.02. The dimensions of the cage were 0.27m (10.7") x 0.16m (6.38") x 0.21m (8.39") high, which maintained the volume of the original cage that had sloped sides. The sides of the cage were modeled as thin plates, with the thickness and conductivity of the plates set to those of the physical cage polycarbonate. The water bottle and food normally found in a cage were modeled as a single block in order to reduce the computational overhead. The volume of the block was the same as that of the bottle and food combined. The bedding of the cage was included as a rectangular block of 0.27m (10.7") x 0.16m (6.38") x 1.27e-2m (0.5").

The mice were modeled as a block of 0.11m (4.25") x 8.57e-2m (3.38") x 0.22m (0.88"), the same representation that was used in the experimental cage wind tunnel tests (see volume I, section 4.1.1). This simulated the effect of 'huddling' by the mice. The surface temperature of the block was fixed at 30.0 °C (86.0 °F), which is agreed to be a typical mouse body surface temperature.

Surrounding this block, a source of CO₂ was defined at 2.12e-7 kg/s (0.76g/hr), which was based on the generation rate indicated for the dark period in the early tests on the effect of the

photoperiod on the mice. The supply air was assumed to have a zero concentration of CO₂. This source allowed the additional concentration of CO₂ in the air to be calculated in the simulation. It also allowed the concentration of NH₃, among other things, to be calculated by scaling even though it has a different molecular weight from both air and CO₂. This was possible as the magnitude of the source was very small and the resulting concentrations were so low as to have a negligible effect on the density of the mixture of air, CO₂, and NH₃. In effect, the CO₂ and NH₃ are intimately mixed with, and flow with, the air.

Experimental data later showed the generation rate of CO₂ was actually higher than the source used in the CFD simulations at 0.90 g/hr/100g mouse body weight. This means the concentration of CO₂ in the room and cages was derived from the simulated concentration multiplied by a scaling factor (0.90/0.76). The concentrations of NH₃ in both the cages and the room were also derived by scaling the concentration with a factor specified in the post-processing of the data. This factor was assumed to vary according to the number of days that passed since the bedding in the cage was changed, along with the average relative humidity in the cages. See volume I, section 4.2.1.2 for the experimental determination of the factors.

Background levels of CO₂ and NH₃ were assumed to be zero. This means that all values quoted in the CFD section of the report are relative to the background level. If an absolute value for CO₂ is required, an additional amount in the range of 300ppm to 700ppm should be added for most locations.

The remaining cage boundary conditions are associated with the transfer mechanisms for air/gases to enter/leave the cage. The cracks at the side of the cage were modeled as 6.35e-3m (0.25”) high planar resistances, with the loss coefficient for these resistances having been determined from the cage wind tunnel CFD simulations (see volume I section 4.2.1.2). The top of the cage, which was filtered, was defined as a combination of a planar resistance and a planar source. The determination of the loss coefficient for the resistance, and the coefficient for the source has been outlined (see volume I, section 4.2.1.1).

The spacing of the cages on the shelves was dependent on whether the racks were single density (7 cages per shelf), or double density (14 cages per shelf). In the single density cases, the cages were centrally located in the short dimension, and equally spaced in the long dimension. The spacing was 4.88e-2m (1.92”) from corner of cage to corner of adjacent cage. In the double density racks, the cages were equally spaced in both the long and short dimensions. The spacing was 2.20e-2m (0.87”) and 4.88e-2m (1.92”), respectively.

Change Station Model

Two alternative change stations were considered in this project. Both stations were constructed primarily from rectangular blocks and triangular prisms. The internal structure and flow field were of no concern in this project. It was only the effect of the station on the room airflow that is of importance.

The first design is shown in figure 1.03. The station had overall dimensions of 1.32m (52”) x 0.86m (34”) x 1.83m (72”). This design was effectively passive in terms of direct flow field interaction. In particular, the station internally recirculated a flow of 350 cfm (1.65e-1 m³ /s),

with only 10 percent leakage defined at the sash opening. The makeup air intake for this leakage was mounted at the side of the station. The station dissipated heat that was expected to affect the room's overall flow field. In particular, the station contributed a load of 720W to the room. This heat was mostly confined to the lower portion of the station where the motor was located.

Figure 1.03 *Original Change Station Design*

Due to concerns raised over the relative passiveness of the first station design, a second design was considered, as is displayed in figure 1.04. The station had overall dimensions of 1.50m (59") x 0.86m (34") x 1.93m (76") high. This station also recirculated air, at 300 cfm ($1.42\text{e-}1 \text{ m}^3/\text{s}$), but discharged a much higher percentage than the first design. In particular, 200 cfm ($9.44\text{e-}2 \text{ m}^3/\text{s}$) was discharged through grilles at the top of the station. The air makeup to compensate for this discharge was mounted at the front sill at the opening to the station. The station dissipated 660W, and this heat was considered to be added to the air discharge at the top of the station.

Figure 1.04 *Alternative Change Station Design*

Modeling Assumptions

- Solar load was not modeled through the walls of the room.
- The floor, ceiling, and walls were assumed to have no heat transfer, i.e., the surrounding areas were assumed to be at the same temperatures.
- All surfaces were treated as smooth when calculating surface friction.
- The sink in the animal room was modeled as a single rectangular block. The recess formed by the shape of the sink was not modeled because the effect of the recess would be negligible on the overall flow field within the room.
- No lighting was assumed in the animal room simulations. The reason for this was that higher CO₂ and NH₃ emissions occur during dark (scotophase) conditions (see volume I, section 4.1.2.8.1 and appendix I, sections 3.4.1.9 and 3.4.1.10).

- The animal room was intended to be kept at 22.2 °C (72.0 °F), with temperature control performed on the exhaust air temperature.
- No leakage occurred into or out of the animal room other than that specified through the cracks around the door.
- Air density variations due to temperature were negligible. Density variation was therefore ignored in all terms apart from in the momentum term for the vertical velocity component. This is known as the Boussinesq approximation.
- The levels of CO₂ and NH₃ were so diluted in the whole room simulations, even at their source, that the variation of the mixture density due to differing molecular weights was negligible.

1.2 Whole Room Configurations

To investigate a range of parameters, the basic model described in section 1.1 was modified. Wherever possible, only one parameter was varied at a time to fully assess the effect.

The list of room runs as they were considered is given in table 1.01. Parameters considered in this report are as follows:

- *Supply Diffuser Type*: Three different diffuser types were considered in this project: radial diffusers, low induction diffusers, and slot diffusers. While all these diffuser types are ceiling mounted diffusers, the flow patterns resulting from them are fundamentally different. See volume I, section 4.2.2 and figures 1.05 to 1.07).

Figure 1.05 Radial Diffuser

Figure 1.06 Slot Diffuser

Figure 1.07 *Low Induction Diffuser*

- *Exhaust Location and Number:* Four different exhaust locations were considered: ceiling; high level, low level on the long walls, and low level on the door wall. The number of exhausts used in each of these locations was also considered as a parameter. See figures 1.08 to 1.11.

Figure 1.08 Ceiling Level Exhausts

Figure 1.09 High Level Exhausts

Figure 1.10 *Low Level Exhausts*

Figure 1.11 *Low Level Exhausts on the Door Wall*

- **Room Air Change Rate:** In addition to the basecase ACH of 15, the following three other ACH values were considered: 5, 10, and 20 ACH.

- *Change Station Design and Status:* Two different change station designs were considered, as outlined above. The two designs were intended to present both a passive and intrusive influence on the room volume. In the case of the former design, the station was also considered switched off.
- *Pressurization of Room Relative to Corridor:* The pressurization of a room is dependent on the difference between the supply and exhaust flow rates. A higher exhaust rate than supply leads to negative pressurization of the room; hence, makeup air is supplied to the room via available transfer mechanisms, namely door cracks. In this project, the amount of makeup air allowed through the door cracks was varied between 100 cfm ($4.72\text{e-}1 \text{ m}^3/\text{s}$) into the room to 100 cfm ($4.72\text{e-}1 \text{ m}^3/\text{s}$) out of the room.
- *Orientation of Cage Racks in Room:* The racks were considered both parallel to the long walls, and perpendicular to them. See figures 1.12 and 1.13

Figure 1.12 Racks Parallel to Side Walls

Figure 1.13 Racks Perpendicular to Side Walls

- *Side Cracks of Cage Sealed Instead of Open:* A series of cases was considered in which the side cracks of the cage were sealed, leaving the cage filter top as the only transfer mechanism. The main objective was to establish the relative increase in cage NH_3 and CO_2 levels when the secondary transfer mechanism was removed.
- *Density of Cages:* The number of cages per rack was considered as a parameter. In addition to the basecase value of 42 cages per rack, a double density 84 cages per rack was also considered, as was a reduced density of 28 cages per rack. See figures 1.14 and 1.15.

Figure 1.14 Double Density Rack

Figure 1.15 Reduced Density Rack

- **Location of Change Station:** The location of the change station was swapped with each of the racks in the room. See figures 1.16 to 1.20.

Figure 1.17 Change Station Swapped with Rack 2

Figure 1.18 Change Station Swapped with Rack 3

Figure 1.19 Change Station Swapped with Rack 4

Figure 1.20 Change Station swapped with Rack 5

- *Rack Grouping:* In some series, the racks were considered to be along one wall only, rather than spread out through the room. See figure 1.21.

Figure 1.21 Racks on One Wall Only

- *Room Width:* Three runs were performed with the room width increased to 4.26m (14' 0").

- *Supply Air Temperature:* In a few runs the supply air temperature was raised to 22.2 °C (72.0 °F), at 49 percent RH which would cause the room and exhaust temperatures to be higher than the design value of the baseline case.

3. RANKINGS OF RESULTS OF WHOLE ROOM RUNS

3.1 Introduction

The following tables present rankings of the results of the CFD room simulations based on Room (scientists' breathing zone) and cages mean values for CO₂ and NH₃ (day 4) concentrations, temperature, and relative humidity. The tables start with the case with the lowest value and list the rest in ascending order. The case number should be used to identify all details of the case. The supply diffuser type, exhaust location, supply flow rate, and supply discharge temperature are given to provide a quick overview of the case.

Discussion of these tables can be found in volume I, section 3.3.
